⁶ Summary

⁷ Accurate simulation of granular materials under extreme mechanical conditions, such as crushing, fracture, and large deformation, remains a significant challenge in geotechnical, manufacturing, and mining applications. Classical discrete element method (DEM) models typically treat particles as rigid or nearly rigid bodies, limiting their ability to capture internal deformation and fracture. The PeriDEM library, first introduced in ([Prashant K. Jha et al., 2021](#)), addresses this limitation by modeling particles as deformable solids using peridynamics, a nonlocal continuum theory that naturally accommodates fracture and significant deformation. Inter-particle contact is handled using DEM-inspired local laws, enabling realistic interaction between complex-shaped particles.

¹⁶ Implemented in C++, PeriDEM is designed for extensibility and ease of deployment. It relies on a minimal set of external libraries, supports multithreaded execution, and includes demonstration examples involving compaction, fracture, and rotational dynamics. The framework facilitates granular-scale simulations, supports the development of constitutive models, and serves as a foundation for multi-fidelity coupling in real-world applications.

²¹ Statement of Need

²² Granular materials play a central role in many engineered systems, but modeling their behavior under high loading, deformation, and fragmentation remains an open problem. Popular open-source DEM codes such as YADE ([Smilauer et al., 2021](#)), BlazeDEM ([Govender et al., 2016](#)), Chrono DEM-Engine ([Zhang et al., 2024](#)), and LAMMPS ([Thompson et al., 2022](#)) are widely used but typically treat particles as rigid, limiting their accuracy in scenarios involving internal deformation and breakage. A recent review by Dosta et al. ([Dosta et al., 2024](#)) compares several DEM libraries. Meanwhile, peridynamics-based codes such as Peridigm ([Littlewood et al., 2024](#)) and NLMech ([Prashant K. Jha & Diehl, 2021](#)) are designed to simulate deformation and fracture within a single structure, with limited support for multi-structure simulations.

³¹ PeriDEM fills this gap by integrating state-based peridynamics for intra-particle deformation with DEM-style contact laws for particle interactions. This hybrid approach enables direct simulation of particle fragmentation, stress redistribution, and dynamic failure propagation—capabilities essential for modeling granular compaction, attrition, and crushing.

³⁵ Recent multiscale approaches, including DEM-continuum and DEM-level-set coupling methods ([Harmon et al., 2021](#)), aim to bridge scales but often rely on homogenization assumptions. Sand crushing in geotechnical systems, for example, has been modeled using micro-CT-informed FEM or phenomenological laws ([Chen et al., 2023](#)). PeriDEM offers a particle-resolved alternative that allows bottom-up investigation of granular failure and shape evolution, especially in systems where fragment dynamics are critical.

41 Background

42 The PeriDEM model was introduced in ([Prashant K. Jha et al., 2021](#)), demonstrating its
43 ability to model inter-particle contact and intra-particle fracture for complex-shaped particles.
44 It is briefly described next.

45 Brief Introduction to PeriDEM Model

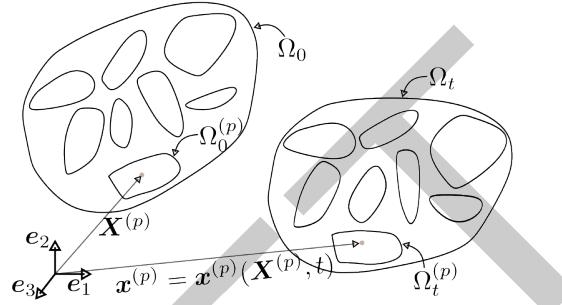

Figure 1: Motion of particle system.

46 Consider a fixed frame of reference and $\{e_i\}_{i=1}^d$ are orthonormal bases. Consider a collection
47 of N_P particles $\Omega_0^{(p)}$, $1 \leq p \leq N_P$, where $\Omega_0^{(p)} \subset \mathbb{R}^d$ with $d = 2, 3$ represents the initial
48 configuration of particle p . Suppose $\Omega_0 \supset \cup_{p=1}^{N_P} \Omega_0^{(p)}$ is the domain containing all particles; see
49 [Figure 1](#). The particles in Ω_0 are dynamically evolving due to external boundary conditions and
50 internal interactions; let $\Omega_t^{(p)}$ denote the configuration of particle p at time $t \in (0, t_F]$, and
51 $\Omega_t \supset \cup_{p=1}^{N_P} \Omega_t^{(p)}$ domain containing all particles at that time. The motion $x^{(p)} = x^{(p)}(X^{(p)}, t)$
52 takes point $X^{(p)} \in \Omega_0^{(p)}$ to $x^{(p)} \in \Omega_t^{(p)}$, and collectively, the motion is given by $x = x(X, t) \in$
53 Ω_t for $X \in \Omega_0$. We assume the media is dry and not influenced by factors other than
54 mechanical loading (e.g., moisture and temperature are not considered). The configuration of
55 particles in Ω_t at time t depends on various factors, such as material and geometrical properties,
56 contact mechanism, and external loading. Essentially, there are two types of interactions
57 present in the media:

- 58 ▪ *Intra-particle interaction* that models the deformation and internal forces in the particle
59 and
- 60 ▪ *Inter-particle interaction* that accounts for the contact between particles and the boundary
61 of the domain in which the particles are contained.

62 In DEM, the first interaction is ignored, assuming that particle deformation is insignificant
63 compared to inter-particle interactions. On the other hand, PeriDEM accounts for both
64 interactions.

65 The balance of linear momentum for particle p , $1 \leq p \leq N_P$, takes the form:

$$\rho^{(p)} \ddot{\mathbf{u}}^{(p)}(\mathbf{X}, t) = \mathbf{f}_{int}^{(p)}(\mathbf{X}, t) + \mathbf{f}_{ext}^{(p)}(\mathbf{X}, t), \quad \forall (\mathbf{X}, t) \in \Omega_0^{(p)} \times (0, t_F], \quad (1)$$

66 where $\rho^{(p)}$, $\mathbf{f}_{int}^{(p)}$, and $\mathbf{f}_{ext}^{(p)}$ are density, and internal and external force densities. The
67 above equation is complemented with initial conditions, $\mathbf{u}^{(p)}(\mathbf{X}, 0) = \mathbf{u}_0^{(p)}(\mathbf{X})$, $\dot{\mathbf{u}}^{(p)}(\mathbf{X}, 0) =$
68 $\dot{\mathbf{u}}_0^{(p)}(\mathbf{X})$, $\mathbf{X} \in \Omega_0^{(p)}$.

69 Internal force – State-based peridynamics

70 The internal force term $f_{int}^{(p)}(\mathbf{X}, t)$ in the momentum balance governs intra-particle deformation
71 and fracture. In PeriDEM, this term is modeled using a simplified state-based peridynamics
72 formulation that accounts for nonlocal interactions over a finite horizon. The underlying model
73 and its numerical implementation are discussed in detail in [([Prashant K. Jha et al., 2021](#)),
74 Sections 2.1 and 2.3].

75 DEM-inspired contact forces

76 The external force term $f_{ext}^{(p)}(\mathbf{X}, t)$ includes body forces, wall-particle interactions, and contact
77 forces from other particles. Contact is modeled using a spring-dashpot-slider formulation
78 applied locally when particles come within a critical distance; see [Figure 2](#). This approach
79 introduces nonlinear normal forces, damping, and friction without relying on particle convexity
80 or geometric simplifications. The full formulation of contact detection, force assembly, and
81 implementation is detailed in [[\(Prashant K. Jha et al., 2021\)](#), Section 2.2].

82 Implementation

83 PeriDEM is implemented in C++ and hosted on GitHub. It depends on a minimal set of
84 external libraries, most of which are bundled in the external directory. Key dependencies
85 include Taskflow ([Huang et al., 2021](#)) for multithreaded parallelism, nanoflann ([Blanco &](#)
86 [Rai, 2014](#)) for efficient neighborhood search, and VTK for output. The numerical strategies
87 for neighbor search, peridynamic integration, damage evaluation, and time stepping follow
88 those introduced in [[\(Prashant K. Jha et al., 2021\)](#), Section 3]. The core simulation model
89 is implemented in [src/model/dem](#), with the class `DEMModel` managing particle states, force
90 calculations, and time integration. This work builds on earlier research in the analysis and
91 numerical methods for peridynamics; see ([Prashant K. Jha et al., 2025](#); [Prashant K. Jha & Lipton, 2018a, 2018b, 2019](#); [Prashant K. Jha & Lipton, 2020](#)).

93 Features

- 94 ▪ Combines peridynamics and DEM to model intra-particle deformation and inter-particle
95 contact
- 96
- 97 ▪ Simulates deformation and breakage of single particles under complex loading conditions

- 99 ▪ Supports arbitrarily shaped particles for realistic granular systems
- 100
- 101 ▪ Ongoing development of MPI-based parallelism and adaptive modeling strategies to
- 102 improve efficiency without sacrificing accuracy

103 Examples

104 Example cases are described in [examples/README.md](#). One key simulation demonstrates
 105 the compression of over 500 circular and hexagonal particles in a rectangular container by
 106 displacing the top wall. The stress on the wall becomes increasingly nonlinear with penetration
 107 depth as damage accumulates and the medium yields (see [Figure 3a](#)).

108 Preliminary performance tests show that compute time increases exponentially with particle
 109 count due to the nonlocal nature of both peridynamic and contact interactions—highlighting
 110 a computational bottleneck. This motivates future integration of MPI-based parallelism and
 111 a multi-fidelity modeling framework. Additional examples include attrition of non-circular
 112 particles in a rotating cylinder ([Figure 3c](#)).
